Anza Hiring Team

Re: Senior Software Engineer, Generalist

Dear Anza Hiring Team,

I am applying for the Senior Software Engineer, Generalist role because Anza is working on the part of Solana I want to move closer to: core infrastructure where performance, reliability, security, and open implementation quality matter to the whole network. My background is not a generic Web3 background. I have been building and operating Solana systems where transaction behavior, wallet safety, latency, observability, and failure modes have immediate consequences for real users.

I built and operate SolPulse, a live Solana trading platform across web, Android, and the Solana dApp Store with 350+ users. The system includes automated execution, sniper and DCA flows, limit orders, smart TP/SL exits, multi-DEX routing, priority-fee controls, token intelligence, risk limits, and real-time logs. Building it forced the engineering work Anza describes in the posting: measuring bottlenecks, debugging production behavior, reasoning about race conditions and idempotency, and designing reliability controls around systems that handle real capital.

My other strongest match is infrastructure at the Solana wallet and SDK layer. I authored first-of-their-kind Solana Mobile Wallet Adapter SDKs for Cocos Creator and Unreal Engine 5, including an Android bridge with encrypted wallet association, a zero-dependency transaction serializer/Base58/RPC core for Cocos, and a C++/Blueprint surface over the official Kotlin client library for Unreal. I verified signing flows on Solana Seeker hardware across Phantom, Solflare, Backpack, Jupiter, and Seed Vault, and contributed merged fixes upstream to public Godot and Unity Solana SDKs.

That work maps directly to Anza's need for engineers who can analyze unfamiliar code, collaborate with subject-matter experts, benchmark practical solutions, and document architecture clearly. I am comfortable moving between product-facing Solana behavior and lower-level implementation details: transaction construction, signing boundaries, mobile security constraints, RPC behavior, logs, metrics, and the tradeoffs between developer ergonomics and protocol safety.

I would be excited to bring production Solana ownership, C++ systems integration, adversarial thinking around wallet and transaction safety, and open-source SDK discipline to Anza. I know Agave is a deeper infrastructure surface than most application work, and that is exactly the appeal. I would welcome the chance to discuss how my experience operating Solana systems above the client can translate into stronger performance and reliability work inside the client and the broader network.

Sincerely,

Mathew Stevens
